MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

The complete sequence of the 16,569-base pair human mitochondrial genome is presented. The genes for the 12S and 16S rRNAs, 22 tRNAs, cytochrome c oxidase subunits I, II and III, ATPase subunit 6, cytochrome b and eight other predicted protein coding genes have been located. The sequence shows extreme economy in that the genes have none or only a few noncoding bases between them, and in many cases the termination codons are not coded in the DNA but are created post-transcriptionally by polyadenylation of the mRNAs.

Mitochondrial DNA Mutation Associated with Leber's Hereditary Optic Neuropathy

DOUGLAS C. WALLACE,* GURPARKASH SINGH, MARIE T. LOTT, JUDY A. HODGE, THEODORE G. SCHURR, ANGELA M. S. LEZZA, LOUIS J. ELSAS II, EEVA K. NIKOSKELAINEN

Leber's hereditary optic neuropathy is a maternally inherited disease resulting in optic nerve degeneration and cardiac dysrhythmia. A mitochondrial DNA replacement mutation was identified that correlated with this disease in multiple families. This mutation converted a highly conserved arginine to a histidine at codon 340 in the NADH dehydrogenase subunit 4 gene and eliminated an Sfa NI site, thus providing a simple diagnostic test. This finding demonstrated that a nucleotide change in a mitochondrial DNA energy production gene can result in a neurological disease.

NATURE VOL. 331 25 FEBRUARY 1988

Deletions of muscle mitochondrial DNA in patients with mitochondrial myopathies

I. J. Holt, A. E. Harding & J. A. Morgan-Hughes

Department of Clinical Neurology, Institute of Neurology, Queen Square, London WC1N 3BG, UK

***In vitro* studies of muscle mitochondrial metabolism in patients with mitochondrial myopathy have identified a variety of functional defects of the mitochondrial respiratory chain, predominantly affecting complex I (NADH-CoQ reductase) or complex III (ubiquinol–cytochrome *c* reductase) in adult cases[1–3]. These two enzymes consist of ~36 subunits, eight of which are encoded by mitochondrial DNA (mtDNA)[4–6]. The increased incidence of maternal, as opposed to paternal, transmission in familial mitochondrial myopathy suggests that these disorders may be caused by mutations of mtDNA[7,8]. Multiple restriction endonuclease analysis of leukocyte mtDNA from patients with the disease, and their relatives, showed no differences in cleavage patterns between affected and unaffected individuals in any single maternal line. When muscle mtDNA was studied, nine of 25 patients were found to have two populations of muscle mtDNA, one of which had deletions of up to 7 kilobases in length. These observations demonstrate that mtDNA heteroplasmy can occur in man and that human disease may be associated with defects of the mitochondrial genome.**

MELAS syndrome:
Characteristic migrainous and epileptic features and maternal transmission

P. Montagna, MD; R. Gallassi, MD; R. Medori, MD; E. Govoni, MD; M. Zeviani, MD; S. Di Mauro, MD; E. Lugaresi, MD; and F. Andermann, MD

Article abstract—Severe prolonged migrainous symptoms and prolonged partial status epilepticus are characteristic features of the MELAS syndrome (mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes). Maternal transmission previously found in myoclonus epilepsy and ragged-red fibers (MERRF), another mitochondrial disease, is suggested in this disorder as well.

Article abstract—Three siblings of a family affected with Leber's hereditary optic neuropathy (LHON) showed a mitochondrial DNA mutation at position 11778. The lactate response to a standardized effort was increased in only one case. Muscle biopsies and biochemistry of muscle and platelet mitochondrial enzymes were normal. All patients showed an altered energy metabolism during exercise and during recovery after exercise on phosphorus 31-magnetic resonance spectroscopy (^{31}P-MRS) of muscle. Brain ^{31}P-MRS showed a decreased energy reserve (decreased PCr/Pi ratio) in all patients. ^{31}P-MRS noninvasively demonstrated an altered mitochondrial energy metabolism in muscle and, for the first time, in the brains of LHON patients.

UGA	STOP	Tryptophan	Tryptophan	Tryptophan
AGA, AGG	Arginine	STOP	Serine	Arginine
AUA	Isoleucine	Methionine	Methionine	Methionine
AUU	Isoleucine	Methionine	Methionine	Methionine
CUU, CUC, CUA, CUG	Leucine	Leucine	Leucine	Threonine

MtDNA is the only source of critical cellular proteins outside of the eukaryotic nucleus. In the majority of eukaryotes, mtDNA is organizsed as a circular, double-stranded DNA molecule (Fig. 1).[5] The strands are distinguished by their nucleotide composition: heavy (H-strand) is guanine rich, compared with the cytosine-rich light strand (L-strand). The length varies between species (15 000–17 000 bp), but is fairly consistent in humans (~16 569 bp).[5] MtDNA is a multi-copy DNA, with cells containing between 100 and 10 000 copies of mtDNA (dependent upon cellular energy demand).

mtDNA structure

Gene	Map Locus[a]	Abbreviation	Location[b]

mtDNA REPLISOME

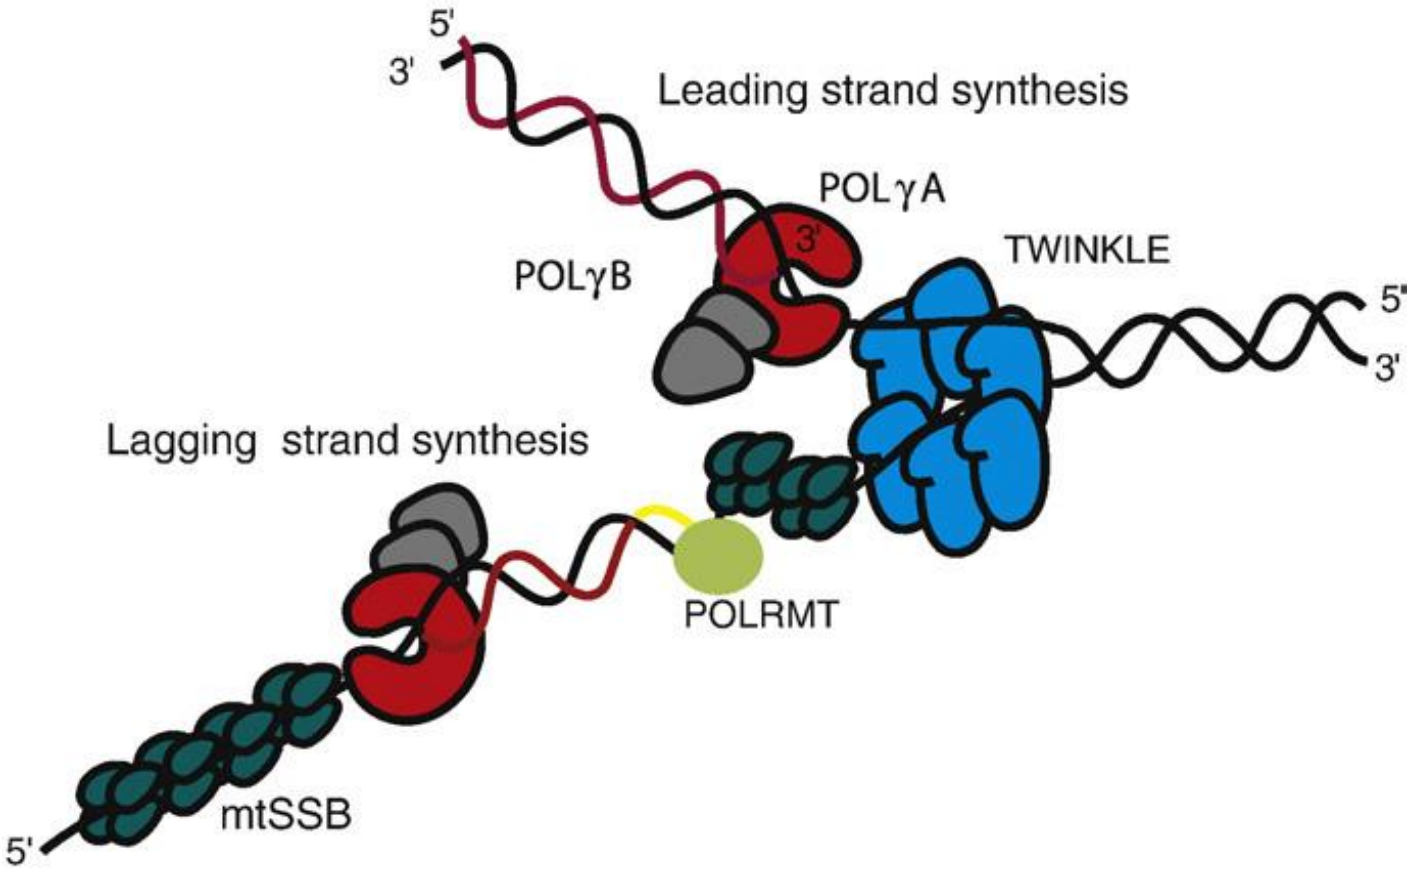

Fig. 2. The mtDNA replication machinery. The TWINKLE helicase (blue) moves in a 5' to 3' direction while unwinding dsDNA. The mtSSB protein (dark green) stabilizes the single stranded conformation and stimulates the DNA synthesis by the POLγ (red (A) and gray (B)). POLRMT (light green) synthesizes the RNA primer (yellow line) needed for lagging strand DNA synthesis.

Super-resolution microscopy reveals that mammalian mitochondrial nucleoids have a uniform size and frequently contain a single copy of mtDNA

Christian Kukat[a,1], Christian A. Wurm[b,c,1], Henrik Spåhr[a], Maria Falkenberg[d], Nils-Göran Larsson[a,2], and Stefan Jakobs[b,c,2]

[a]Department of Mitochondrial Biology, Max Planck Institute for Biology of Ageing, D-50931 Cologne, Germany; [b]Department of NanoBiophotonics, Mitochondrial Structure and Dynamics Group, Max Planck Institute for Biophysical Chemistry, and [c]Department of Neurology, University of Göttingen, D-37077 Göttingen, Germany; and [d]Department of Medical Biochemistry and Cell Biology, University of Gothenburg; SE-40530 Gothenburg, Sweden

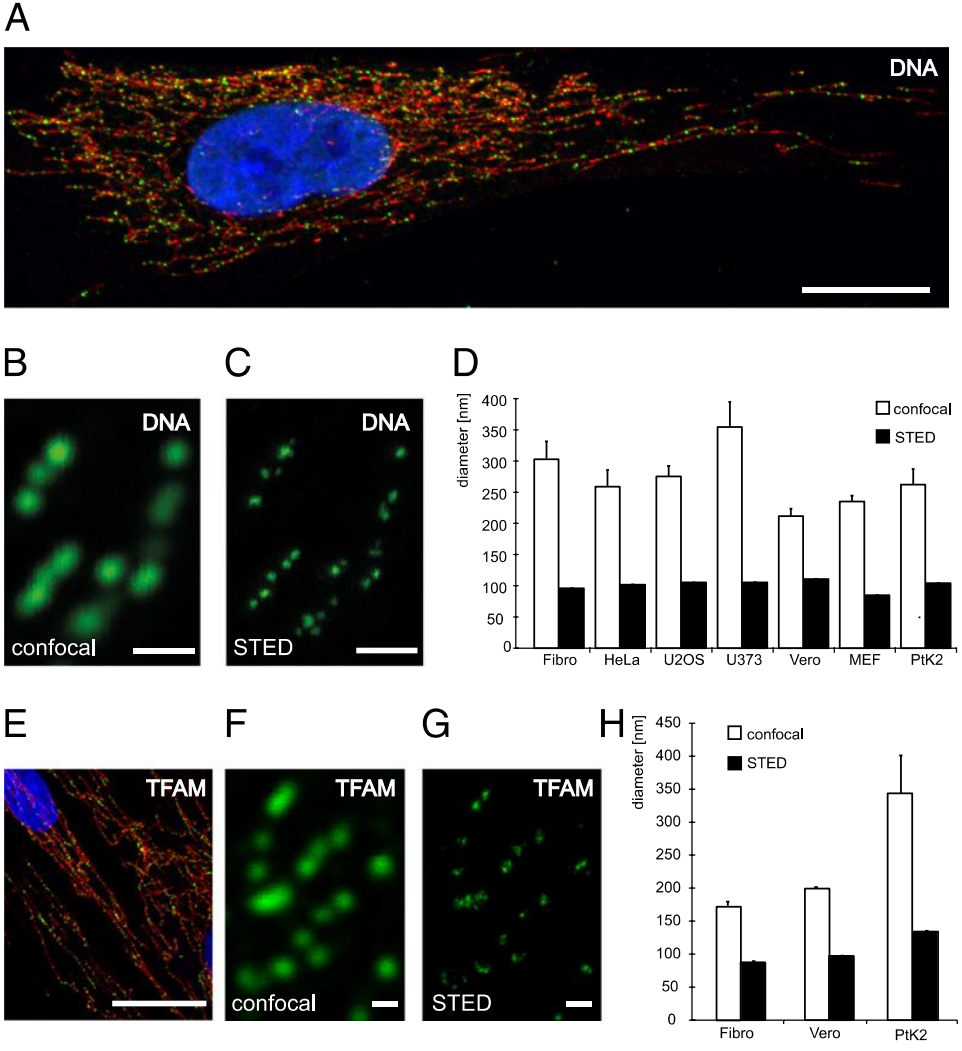

Fig. 1. The nucleoid has a uniform mean size in mammalian cells. (*A*) mtDNA (green, DNA antibodies) is localized in nucleoids in the tubular mitochondria (red, anti-TOM20) of human fibroblasts. DAPI-staining of nucleus in blue. (*B*) Using confocal microscopy, nucleoids labeled with an antiserum against DNA appear to be solid structures with an average diameter of ~300 nm in human fibroblasts. (*C*) Applying super-resolution STED microscopy, we found that the apparent nucleoids, as detected by confocal microscopy, frequently are agglomerates of several smaller structures, each with an average diameter of ~99 nm. The section shown is the same as the one in *B*. (*D*) Sizes of nucleoids labeled with a DNA antibody determined by confocal and STED imaging in mammalian cell lines, such as, human primary culture fibroblasts (Fibro), human cervix adenocarcinoma cells (HeLa), human osteosarcoma cells (U2OS), human glioblastoma cells (U373), mouse embryonic fibroblasts (MEF), African green monkey kidney epithelial cells (Vero), and potoroo kidney cells (PtK2). The indicated sizes denote the antibody labeled nucleoids. (*E*) TFAM (green, anti-TFAM) is located in nucleoids in the mitochondrial network (red, anti-TOM20) of human fibroblasts. Nuclear DAPI-staining in blue. (*F*) Using confocal microscopy, the nucleoids labeled with an antiserum against TFAM appear in a punctuate pattern. (*G*) STED microscopy reveals a mean diameter of ~88 nm for nucleoids labeled with a TFAM antibody in human fibroblasts. The section shown is the same as the one in *F*. (*H*) Quantification of the sizes of nucleoids labeled with TFAM antibodies determined by confocal and STED imaging in three mammalian cell lines. Error bars indicate SEM. (Scale bars: 20 μm in *A* and *E*, 0.5 μm in *B*, *C*, *F*, and *G*.)

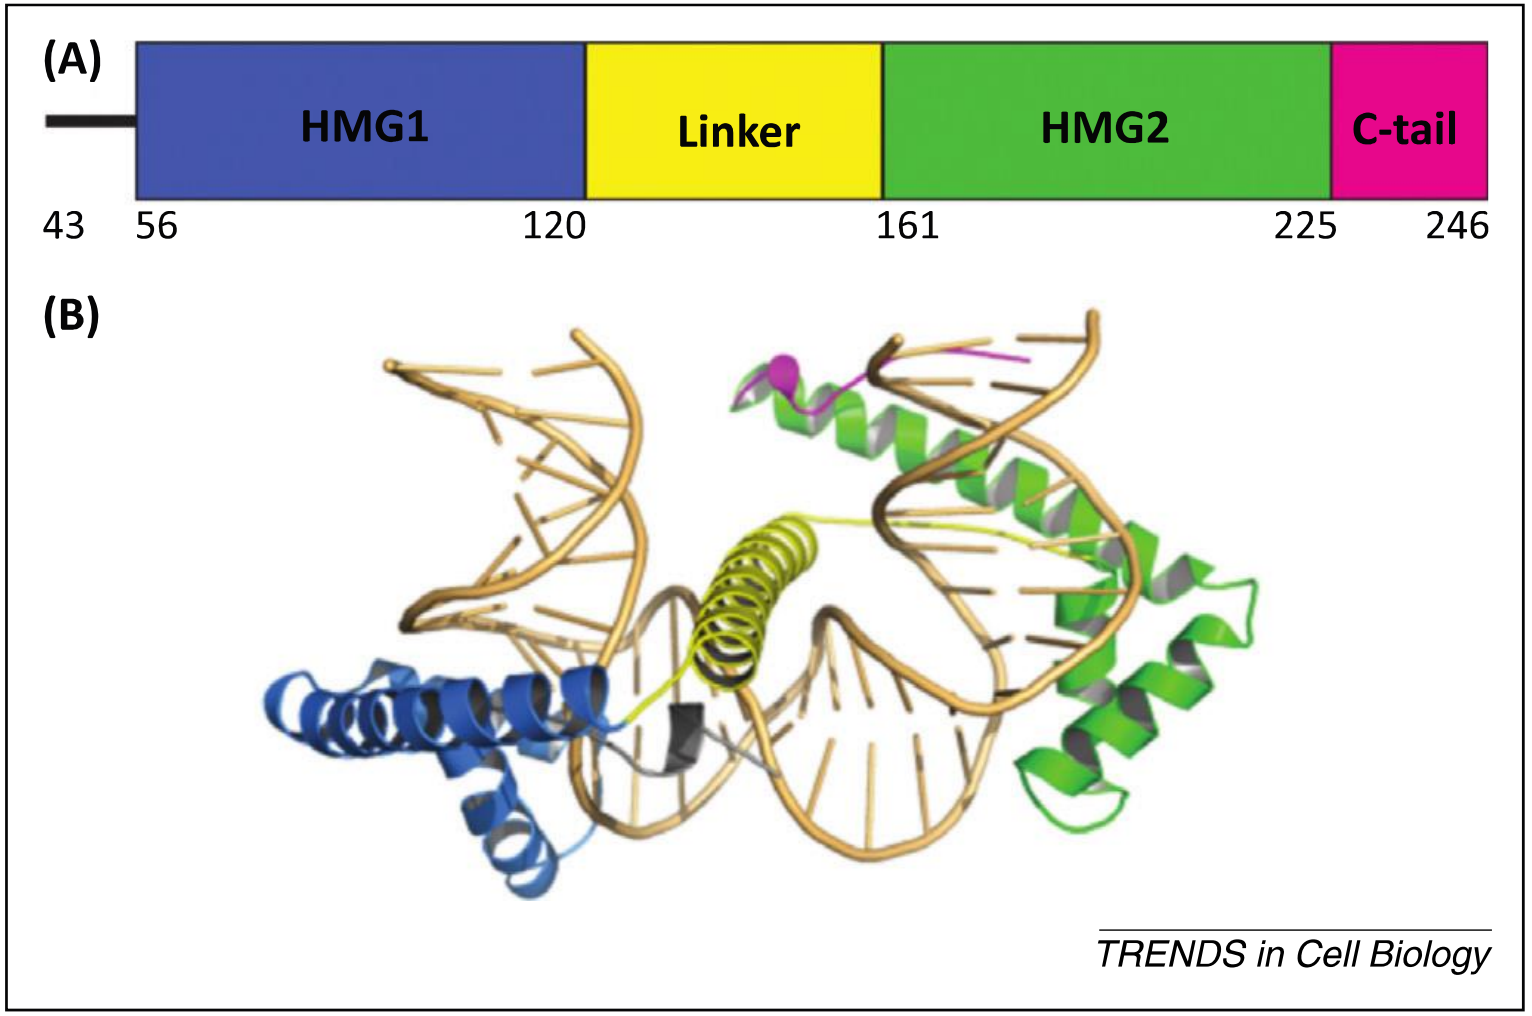

Figure 1. The structure of the mitochondrial transcription factor A (TFAM). **(A)** Domain structure of mature TFAM; numbers indicate amino acids. Amino acids 1–42 form the mitochondrial targeting sequence that is cleaved upon import of TFAM into the mitochondrial matrix. HMG, high mobility group domain; C-tail, C-terminal tail. **(B)** The TFAM–DNA complex. TFAM in complex with 28 bp LSP (light strand promoter) DNA [14] induces a U-turn into the DNA strand. TFAM domains are color-coded as in (A) and DNA is colored in beige.

CONCLUSIONS

- Unexpectedly, we identified a new disease characterized by mtDNA depletion in adults and associated with a prevalent ocular and kidney phenotype
- Mitochondrial SSBP1 carried dominant de novo pathogenic mutations, and in one case a recessive homozygous mutation
- The current findings enlarge the landscape of diseases of mtDNA maintenance
- In deep dissection of the pathogenic mechanisms will increase our understanding of mtDNA replication and control of mtDNA copy number
